

One hospital management platform. Every hospital gets its own address, its own data, its own rules.

Netcare is multi-tenant hospital management software: a single, continuously-improved platform that many hospitals run on at once, each on its own subdomain, each seeing only its own patients, staff and records. You get the economics of shared software and the isolation of a system built just for you.

yourhospital.netcare.co.in

motherkraft.netcare.co.in

...

ONBOARDING A new hospital gets its own subdomain and first admin account the same day — no custom install, no consultant on-site.	ACCESS CONTROL 6 roles out of the box. Your superadmin can add more and edit exactly what each one can see — no ticket to us, no redeploy.
COMPLIANCE-READY Drug licence, NABH, NABL, PCPNDT, HFR ID — tracked with expiry, and only asked for when your hospital's category actually needs it.	DATA ISOLATION Enforced in every database query, and checked automatically before every release ships — not a policy on paper.

Every request answers three questions — never one

Most hospital software conflates "who is this" with "what can they do." Netcare keeps three questions separate on every single action, which is what makes fine-grained, auditable access control possible instead of aspirational.

01 — TENANT

Whose data is this?

Decided once, at login, from the subdomain — and sealed into that session's token as `hospital_id`. It cannot be edited or guessed by the client afterward.

02 — IDENTITY

Who is calling?

The signed-in doctor, nurse, admin or patient — resolved fresh on every request, not assumed from a cached page.

03 — CAPABILITY

Are they allowed to?

Checked against a permission your superadmin granted, at a scope of `own` or `all` — resolved live, so revoking access takes effect immediately, not at next login.

Built on a modern, boring-in-a-good-way stack

Nothing exotic — every choice below is a mainstream, well-supported technology, picked so the platform is fast today and maintainable for years, not a pile of trends.

FRONTEND

Next.js 15 + React 19

Fast page loads, works on any device, no app-store install for staff or patients.

TypeScript, end to end

Whole classes of bugs are caught before they ever reach a hospital's screen.

Tailwind CSS + Radix UI

Consistent, accessible interface components — the same card, table and modal everywhere in the app.

Redux Toolkit (RTK Query)

One disciplined data layer, so every screen reflects the same source of truth.

BACKEND

FastAPI (Python)

Async by default, with request and response shapes enforced by the framework itself.

PostgreSQL + SQLAlchemy 2

A proven relational database for records that must never contradict each other.

Alembic migrations

Every schema change is versioned and reversible — no hand-edited production database.

Pydantic v2, PyJWT, bcrypt

Every payload is validated before it touches the database; passwords and sessions handled to current standards.

INFRASTRUCTURE & INTEGRATIONS

Cloudflare R2 storage

Licence scans, letterheads and reports stored securely, served through signed links only.

Razorpay

Billing and consultation payments through India's leading payment gateway.

Firebase Cloud Messaging

Push notifications to staff and patients — new appointment, result ready, order due.

Resend (transactional email)

Password resets and account notices, delivered reliably from any cloud region.

WHAT'S INSIDE

One system for the whole hospital, not five bolted together

29 backend modules, all permission-gated and tenant-scoped the same way, sharing one login, one patient record and one audit trail — instead of the appointments system, the pharmacy, and the lab being three vendors that don't talk to each other.

FRONT DESK & SCHEDULING

Quick sign-up A name and a phone number is enough to register a patient — email is optional, and a number shared by a family never blocks the next person on it.	Appointments One booking per patient, per department, per day — double-books are refused, not just discouraged.	Departments Category-aware — a maternity hospital and a dental clinic see different defaults.
Schedule blocks Doctors manage their own availability directly.	Consultation fees Set per doctor or department, feeding billing automatically.	

CLINICAL CARE

Patients & records One longitudinal medical record per patient, scoped to your hospital only.	Vitals Recorded by nurses, visible on the chart instantly.	Prescriptions Always attributed to the doctor actually signed in — never a typed-in name.
Video consults Scheduled telemedicine slots built into the same calendar.		

PHARMACY & DIAGNOSTICS

Medicines & inventory Stock levels move with real orders, not a guess.	Medication orders Dispensing refuses outright on short or expired stock.	Injectables & orders Its own stock ledger — separate from oral medicine inventory.
Lab tests, orders & results Order, run, and release results, with a review step before they reach a patient.		

MATERNITY & CHILD HEALTH

Pregnancy records & ANC visits Purpose-built for maternity and multi-specialty hospitals alike.	Babies Linked to the mother's record from birth.	Growth measurements Tracked against standard growth curves over time.
Immunizations Schedule and completion tracked per child.		

Payments Invoices generated by the server — never a number the client can edit.	Consents Purpose-tied consent records for sensitive procedures and data sharing.	Audit logs Who did what, when — kept even if the record itself is later deleted.
Roles & permissions Your superadmin's control panel — no engineering request needed.	Hospital onboarding Legal identity, licences, documents and subscription — one guided wizard.	Notifications Push and email, wired into the events that matter.

DATA SECURITY

Security isn't a policy document here — it's enforced in code

A hospital handles some of the most sensitive data there is. Netcare treats security as an architectural property, checked on every request and every release, rather than a promise made in a sales conversation.

IDENTITY & ACCESS

Passwords, hashed

Stored with bcrypt — never in plain text, never in a log line.

Sealed session tokens

Each login token carries a signed, tamper-proof hospital_id and an expiry — it cannot be edited or replayed against another tenant.

Live permission checks

Access is resolved fresh from the role grant on every request, not cached in the token — revoke a permission and it's gone immediately, not "at next login."

TENANT ISOLATION

One shared enforcement path

Every table carries a hospital_id, and every query runs through the same scoping helper — there's no second code path that could forget it.

Tested, not assumed

An automated suite runs before every release specifically trying to leak one hospital's data into another, and blocks the release if it can.

Silent on probing

A record that doesn't exist and one that isn't yours return the identical "not found" — so guessing at other hospitals' or patients' record numbers reveals nothing.

DOCUMENTS & STORAGE

Signed access only

Licence scans, letterheads and reports are stored behind an opaque reference; the browser is only ever handed a signed, time-limited link, never a direct path into storage.

Encrypted in transit

All traffic to and from the platform runs over HTTPS.

Deletion is a platform decision

Permanently erasing a patient, doctor or clinical record is reserved for the platform owner — no hospital admin account can do it by accident or misuse.

ACCOUNTABILITY

Purpose-tied consent

Consent for a procedure or for sharing data is its own record, tied to a stated purpose — never a single blanket checkbox.

Audit trail that outlives the record

Who did what, and when, is logged and kept even if the record it describes is later removed.

Server-authored facts

Invoice totals, verification timestamps and result-release times are written by the server only — never a value the client can submit.

RELIABILITY & OWNERSHIP

Built to stay up — and built to stay yours

A hospital system has to outlast any single vendor relationship. Netcare is built so your uptime and your data don't depend on taking our word for it.

RELIABILITY

Versioned, reversible schema

Every database change ships as a reviewed Alembic migration — never a hand-edit on a live system.

Separated by design

The application, the database and file storage are three independent systems — scaling or restarting one never puts the others at risk.

Validated before it's stored

Every request is checked against a strict schema before it reaches the database — malformed data is rejected, not silently saved.

OWNERSHIP

Standard, not proprietary

Your records live in a standard PostgreSQL database, cleanly scoped to your hospital — not a format only we can open.

Cleanly yours

Every row your hospital owns carries your hospital's own id — a clean, filterable slice of the schema, never tangled with anyone else's.

No architectural lock-in

Nothing about how the platform is built depends on making your data hard to leave with.

Netcare vs. a typical hospital system

Most hospital software in the market was designed for one installation at a time, with permissions and safety rules written into the code rather than the product. Here's the practical difference that makes for a hospital choosing between them.

QUESTION	NETCARE	TYPICAL LEGACY HMS
Getting a new hospital live	Self-serve wizard; a working subdomain and admin account the same day.	Weeks of on-site setup and custom configuration per installation.
Registering a new patient	A name and a phone number is enough — email is optional everywhere, and a phone shared across a family never blocks registering the next person on it.	Often demands a unique email or phone per person, which breaks the moment a household shares one number.
Changing who can do what	Your superadmin edits a permission grid; it applies immediately.	Roles are hardcoded — a new access rule means a developer ticket and a release.
One hospital seeing another's data	Structurally impossible — enforced on every query, and an automated test suite specifically tries to break it before every release.	Isolation is assumed, rarely tested, and shared databases are common.
Deleting a patient or clinical record	Reserved for the platform owner by design; your admins keep full edit rights.	Any admin account can permanently erase a record with one click.
Statutory paperwork	A built-in catalog — HFR ID, NABH, NABL, PCPNDT, drug licence — matched to your category, with expiry tracking.	Generic forms, or tracked outside the system entirely in spreadsheets.

QUESTION	NETCARE	TYPICAL LEGACY HMS
Pharmacy stock accuracy	Moves only by the real quantity on an order; dispensing refuses on short or expired stock.	Often estimated from a dosage string, or not reconciled at all.
Where staff can use it	Any modern browser, any device — nothing to install.	Frequently a desktop client, often Windows-only.
Facts like invoices and timestamps	Always written by the server — never a value the client submits.	Client-submitted values are often trusted as-is.

CRAFT

The details we sweat so your staff don't have to

PHARMACY

Dispensing refuses outright on short or expired stock — a prescription never quietly turns into an inventory discrepancy nobody can explain at month-end.

APPOINTMENTS

One patient can't be double-booked into the same department on the same day — the second attempt is refused before it happens, not untangled afterward at the front desk.

REPORTING

One shared date filter, everywhere — pick a single day or a range once, and appointments, vitals and billing all honor it the same way, instead of three screens with three different date pickers.

BILLING

Injectables and lab charges land on one combined invoice — a patient checking out after a visit isn't handed two bills for one appointment.

DOCUMENTS

A letterhead upload is checked before it's stored — for A4 proportions and print resolution, so a prescription doesn't come out blurry or mis-sized months later.

ONBOARDING

A hospital's identity and its subscription are separate records — a verified, compliant hospital can still be paused for non-payment without touching its clinical data, and reactivated without re-verifying a thing.

LOOKING AHEAD

Where the platform is headed next

Netcare already runs the full patient journey — front desk through pharmacy through billing. These are the items on the near-term roadmap, in the order we're building them.

01 **Registration by ID lookup**

A doctor or nurse registers with just their council licence number and their verified details are pulled in automatically; a patient registers with their Aadhaar number and the rest of the form fills itself in — less typing and fewer errors at the front desk.

02 **Owner-level analytics**

A dashboard for hospital leadership, not just the front desk — patient footfall, revenue trends, doctor utilization and department load, drawn from the same data every other screen already writes to.

03 **Deeper telemedicine**

Scheduled video-consult slots already exist end to end; next is in-call tooling — shared notes and prescription capture during the call itself.

04 **WhatsApp notifications**

Alongside today's push and email alerts, for hospitals whose patients live in WhatsApp.

05 **Native mobile apps**

The web app is fully responsive today; dedicated iOS and Android apps are next for offline-friendly, on-the-ward use.

06 **AI-assisted care**

Drafting consultation notes and discharge summaries from a visit, flagging lab results that fall outside the normal range for a second look, and handling a patient's routine questions before they reach the front desk.

IN SHORT

**Software built the way a
hospital is actually run
— one record, one set of
rules, one place to look.**

Not a spreadsheet with a login screen, and not five disconnected tools wearing one logo. Netcare is one platform where the front desk, the ward, the pharmacy and the lab all read the same patient record — with the access control and the paperwork trail a real hospital, and a real regulator, expects. We'd welcome the chance to walk your team through it live.
